

Calculate the minimum number of grams of AgCl that must be added to 250ml of water in order to form a precipitate. $K_{sp} = 1.8 \times 10^{-10}$ for AgCl

Solution:

Silver chloride dissociates in solution according to the equation: $\text{AgCl} \leftrightarrow \text{Ag}^+ + \text{Cl}^-$

The solubility product of silver chloride is given in the problem condition. Write down his expression: $K_{sp} = [\text{Ag}^+] \times [\text{Cl}^-] = 1.8 \times 10^{-10}$.

Then, from the equation of dissociation of silver chloride should: $[\text{Ag}^+] = [\text{Cl}^-] = s$.

We substitute the unknown accepted by us into the equation for the product of solubility:

$$K_{sp} = [\text{Ag}^+] \times [\text{Cl}^-] = s \times s = s^2 = 1.8 \times 10^{-10}. \text{ Find } s: s = \sqrt{1.8 \times 10^{-10}} = 1.3 \times 10^{-5} \frac{\text{mol}}{\text{L}}.$$

We convert the solubility from the moles dimension per liter to the gram dimension per liter by multiplying the obtained value by the molar mass of silver chloride, which is $143.34 \frac{\text{g}}{\text{mol}}$:

$$s' = 1.3 \times 10^{-5} \times 143.34 = 1.86 \times 10^{-3} \frac{\text{g}}{\text{L}}.$$

Now we find the minimum amount of grams of silver chloride to be added to 250 ml of water:

$$m(\text{AgCl}) = s' \times V(\text{water}) = 1.86 \times 10^{-3} \times 250 \times 10^{-3} = 0.465 \times 10^{-3} \text{ g}.$$

Answer: $0.465 \times 10^{-3} \text{ g}$
