

32 mL of ethanol with an initial temperature of 11 degree C absorbs 562 J of heat. Find the final temperature of the ethanol. (Density of ethanol= 0.789 g/mL)

**Solution:**

$$\rho = \frac{m}{V}$$

**m**-mass

**V**-volume

**$\rho$** -density

$$m = V * \rho$$

1)  $m = 0.789 * 32 = 25.248\text{g}$

$$Q = c * m * \Delta T$$

**c**-the heat capacity of ethanol(2.46 J/gC- from source)

**m**-mass

**Q**-energy(heat)

2)  $\Delta T = Q/m/c = 562/25.248/2.46 = 9.05\text{ }^{\circ}\text{C}$

$$\Delta T = T_{final} - T_{initial}$$

3)  $T_{final} = \Delta T + T_{initial} = 11 + 9.05 = 20.05\text{ }^{\circ}\text{C}$

**Answer: 20.05 °C**
