

Question #79449

The rate of a standard reaction is 0.01840 M/s at 25 °C. It is determined that this is too fast, and that the rate should be reduced to 0.0046 M/s. What temperature should the reaction be run at to achieve this?

- A. 45 °C
- B. 20 °C
- C. 15 °C
- D. 5 °C
- E. 0 °C

Answer:

The right answer is D. 5 °C.

According to the equation [1]:

$$\frac{R_2}{R_1} = Q_{10}^{\frac{T_2 - T_1}{10}},$$

where R_1 – is the rate of reaction at 25°C, R_2 – is the rate of reduced reaction, T_1 – is the temperature of standard reaction ($T_1 = 25 + 273 = 298$ K), T_2 – is the temperature of reduced reaction (in K), Q_{10} – is the Q_{10} temperature coefficient.

For most biological systems, the Q_{10} value is ~ 2 to 3.

$$\frac{0.0046}{0.0184} = Q_{10}^{\frac{T_2 - 298}{10}}$$

$$0.25 = Q_{10}^{\frac{T_2 - 298}{10}}$$

If we suggest that Q_{10} is equal to 2, we get the following:

$$0.25 = 2^{\frac{T_2 - 298}{10}}$$

T_2 should be equal to 278, to be the solution of the equation.

$$t_2 = 278 - 273 = 5 \text{ °C.}$$

So, the right answer is D. 5 °C.
