## Answer on Question \#73120 - Math - Statistics and Probability

## Question

If I toss 2 coins at the same time for 60 times, what will be the probability distribution of heads or tails occurring per toss?

## Solution

It does not matter how many times we toss 2 coins. The probability distribution of heads or tails occurring per one toss will be the same.

When we toss two coins simultaneously, then the possible outcomes are: (two heads) or (one head and one tail) or (two tails) i.e., in short $(\mathrm{H}, \mathrm{H})$ or $(\mathrm{H}, \mathrm{T})$ or $(\mathrm{T}, \mathrm{T})$ respectively, where H is denoted for head and T is denoted for tail.

The sample space is given by $S=\{H H, H T, T H, T T\}$.
Therefore,

$$
\begin{gathered}
p_{1}=P(H H)=\frac{n(H H)}{n(S)}=\frac{1}{4} ; p_{2}=P(\mathrm{HT} \cup \mathrm{TH})=\frac{n(\mathrm{HT} \cup \mathrm{TH})}{n(S)}=\frac{2}{4}=\frac{1}{2} \\
p_{3}=P(T T)=\frac{n(T T)}{n(S)}=\frac{1}{4}
\end{gathered}
$$

Let $X$ give the number of heads and $Y$ the number of tails occurred by tossing of 2 coins simultaneously. The random variable $X$, as well as $Y$, has the following probability distribution

$$
\begin{gathered}
P(X=0)=P(T T)=\frac{1}{4} ; P(X=1)=P(\mathrm{HT} \cup \mathrm{TH})=\frac{1}{2} ; P(X=2)=P(H H)=\frac{1}{4} \\
P(Y=0)=\frac{1}{4} ; P(Y=1)=\frac{1}{2} ; P(Y=2)=\frac{1}{4}
\end{gathered}
$$

Actually, X and Y follow the binomial distribution with $\mathrm{n}=2$ and $p=\frac{1}{2}$.
Let us now consider an experiment of tossing 2 coins for 60 times. Let $E_{1}$ denote the event that head occurs 0 times per one toss, $E_{2}$ denote the event that head occurs 1 time per one toss and $E_{3}$ the event that head occurs 2 times per one toss. Then we can consider how many times events $E_{1}, E_{2}$ and $E_{3}$ occur during these 60 times. It is the multinomial distribution. Let us denote the variable which is the number of occurred event $E_{i}(i=1,2,3)$ as $Z_{i}$ and $p_{i}$ be a probability of $E_{i}$. The probability distribution of $Z_{1}, Z_{2}, Z_{3}$ is
$P\left(Z_{1}=k_{1}, Z_{2}=k_{2}, Z_{3}=k_{3}\right)=\frac{60!}{k_{1}!k_{2}!k_{3}!} p_{1}^{k_{1}} p_{2}{ }^{k_{2}} p_{3}{ }^{k_{3}}$, where $k_{i} \in\{0,1, \cdots, 60\}, i=1,2,3$, and
$k_{1}+k_{2}+k_{3}=60$.
