Answer on Question 51121, Physics, Electric Circuits

Question:

A fuse in an electric circuit is designed to open the circuit like a switch when the current exceeds a preset value. If a fuse is made of material that melts when the current density reaches $400 \frac{A}{cm^2}$, what is the diameter of the wire needed to limit the current to 0.30*A*?

Solution:

By the definition of the current density we have:

$$J=\frac{I}{A'}$$

where J is the current density, I is the current flowing through the wire, A is the cross section area of the wire.

So, we can find the cross section area of the wire:

$$A = \frac{I}{J} = \frac{0.30A}{400\frac{A}{cm^2}} = 0.00075cm^2.$$

We know that $A = \pi r^2 = \frac{\pi d^2}{4}$, therefore from this formula we can obtain the diameter of the wire needed to limit the current to 0.30*A*:

$$d = \sqrt{\frac{4A}{\pi}} = \sqrt{\frac{4 \cdot 0.00075 cm^2}{\pi}} = 0.03 cm = 3 \cdot 10^{-4} m.$$

Answer:

 $d = 3 \cdot 10^{-4} m.$
